

# Estimation of entropy for Poisson marked point processes

Patricia Alonso-Ruiz and Evgeny Spodarev

August 9, 2016

## Abstract

In this paper, a kernel estimator of the differential entropy of the mark distribution of a homogeneous Poisson marked point process is proposed. The marks have an absolutely continuous distribution on a compact Riemannian manifold without boundary.  $L^2$  and almost surely consistency of this estimator as well as its asymptotic normality are investigated.

**Keywords:** marked point process, kernel density estimator, central limit theorem, fibre process, Boolean model.

## 1 Introduction

The concept of entropy was introduced by Shannon in the context of information theory [23] and its origin lies in the classical Boltzmann entropy of thermodynamics. In Shannon's original paper, entropy was defined both for discrete and continuous distributions in  $\mathbb{R}^d$ . In the last case it is called *differential entropy* and this notion can be naturally generalized as follows: Let  $P$  be a probability distribution of a random element  $X$  on an abstract measurable phase space  $(M, \mu)$  with probability density  $f$  with respect to  $\mu$ . The entropy of  $X$  is given by

$$\mathcal{E}_f = -\mathbb{E}_P(\log f(X)) = -\int_M f(x) \log f(x) \mu(dx),$$

where the expectation  $\mathbb{E}_P$  is taken with respect to the probability measure  $P$ .

In this paper, we consider a homogeneous Poisson marked point process (MPP) with marks from a compact Riemannian manifold of dimension  $p \geq 1$  without boundary that are assumed to be independent of the process, and investigate the differential entropy of the mark distribution  $\mathcal{E}_f$ . Our motivation for the study of this quantity is its applicability to detect inhomogeneities in materials modeled by MPPs such as fibre-reinforced plastics, where the direction of each fibre corresponds to a marks of the MPP. During the production process of such materials, the direction of the fibres may deviate from the

predefined one and thus give rise to undesirable clusters or deformations. If the deviation is strong, a significant change on the (local) entropy of the directional distribution can be expected. Considering marks with values in a Riemannian manifold makes this method applicable not only to directions but to any other characteristic of interest, for instance fibre length or fibre curvature. Asymptotic properties of such an estimator are important in particular for hypothesis testing.

In the present work, we propose a nonparametric plug-in estimator of the differential entropy  $\mathcal{E}_f$  based on [1]. It requires estimating the density of the distribution of interest in a nonparametric way, which we perform by means of *kernel density estimation*. This technique was introduced for stationary sequences of real random variables by Rosenblatt [20] and Parzen [16], and extended to stationary real random fields in [9]. In the case of finite samples of i.i.d. random vectors on the sphere, nonparametric kernel estimation methods have been studied in [10, 2] and extended to Riemannian manifolds in [18, 14]. Alternative nonparametric estimators for the directional distribution in line and fibre processes have been presented in [15].

The main result of our paper, Theorem 5.7, gives a central limit theorem (CLT) for an estimator of the differential entropy of the mark distribution density  $f$  of a homogeneous Poisson MPP as the observation window grows to  $\mathbb{R}_+^d$  in a regular manner. This result is an application of a more general result (c.f. Corollary 5.2) of this type for sequences of  $m_n$ -dependent random fields proved in Section 5.

The paper is organized as follows: notation and basics of the theory of MPPs are given in Section 2. In Section 3 we construct a nonparametric kernel density estimator of  $f$  and give conditions for its  $L^2$  and almost sure consistency. In Section 4 we introduce the nonparametric estimator  $\hat{\mathcal{E}}_f(B_n)$  of the entropy  $\mathcal{E}_f$  in an observation window  $B_n \subset \mathbb{R}^d$  and prove its  $L^2$ -consistency when the window size grows appropriately. Finally, we present in Section 5 a CLT for random sums of  $m_n$ -dependent random fields (cf. Corollary 5.2) where independence between the random number of summands and the summands themselves is not assumed. A special case of this result is applied to obtain a CLT of the entropy estimator.

## 2 Preliminaries

In this section, we briefly review basic notions from the theory of marked point processes. For an introduction and summary on these and other models of stochastic geometry we refer the reader to e.g. [25, 24].

### 2.1 Poisson marked point processes

In the following,  $\Pi := \{Y_i\}_{i \geq 1}$  will denote a *homogeneous Poisson point process* on  $\mathbb{R}^d$  of intensity  $\lambda > 0$  and  $(M, g)$  a compact smooth Riemannian manifold of dimension  $p$  without boundary and with Riemannian metric  $g$ . We further assume that  $(M, g)$  is

complete, i.e.  $(M, d_g)$  is a complete metric space, where  $d_g$  denotes the geodesic distance induced by the Riemannian metric  $g$ . The associated Riemannian measure will be denoted by  $v_g$ . A detailed construction of this measure can be found e.g. in [21, p. 61]. Note that since  $M$  is compact,  $v_g(M)$  is finite.

To each point  $Y_i \in \Pi$  we attach a mark  $\xi_i \in M$  and assume that marks are i.i.d. random variables independent of the location of the points in  $\Pi$ . The *Poisson marked point process*  $\Psi := \{(Y_i, \xi_i), Y_i \in \Pi\}$  we will work with is a random variable with values in  $\mathcal{N} := \{\varphi \text{ locally finite counting measure on } \mathbb{R}^d \times M\}$ . An important property of this process is *stationarity*, meaning that  $T_y \Psi \stackrel{d}{=} \Psi$  for all  $y \in \mathbb{R}^d$ , where the translation operator  $T_y$  is defined as  $T_y \varphi(B \times L) := \varphi((B + y) \times L)$  for any Borel set  $B \times L \subset \mathbb{R}^d \times M$  and  $\varphi \in \mathcal{N}$ . We will assume that the distribution of a typical mark  $\xi_0$  has a density  $f: M \rightarrow \mathbb{R}$  with respect to the Riemannian volume measure  $v_g$ .

*Example 2.1.* Poisson fibre process (c.f. [25, Section 8]). A *fibre*  $F: [0, 1] \rightarrow \mathbb{R}^2$  is a sufficiently smooth simple curve of finite length and a *fibre process*  $\Phi$  is a random closed subset of  $\mathbb{R}^2$  that can be represented as the union of at most countable many fibres  $F$ . To each fibre, we can attach a mark  $\xi_F \in [0, \ell]$  that represents its (random) length. If the fibre process is Poisson distributed, then  $\Psi = \{(F, \xi_F), F \in \Phi\}$  and  $M = [0, \ell]$ .

*Example 2.2.* Boolean model. Assume  $d \geq 3$  and consider for each  $1 \leq k \leq d - 1$  the Grassmannian  $G(k, d)$ , i.e. the set of all non-oriented  $k$ -dimensional flats in  $\mathbb{R}^d$  that contain the origin (see e.g. [21, p. 186]). This is a compact manifold of dimension  $k(d - k)$ . Furthermore, denote by  $B(o, r)$  the ball of radius  $r$  centered at the origin  $o \in \mathbb{R}^d$ . The homogeneous Poisson point process  $\Pi \subset \mathbb{R}^d$  leads to the Boolean model

$$\Phi := \bigcup_{Y_i \in \Pi} ((B(o, R_i) \cap Z_i) + Y_i),$$

where  $R_i$  and  $Z_i$  are independent copies of the random radius  $R: \Omega \rightarrow [0, r]$  and the random Grassmannian  $Z: \Omega \rightarrow G(k, d)$ , respectively. The particular case  $k = d - 1$  is used in applications to model lamellae structures, whereas the case  $k = 1$  corresponds to a Poisson fibre process with straight fibres. In both cases,  $G(k, d)$  is isomorphic to the half-sphere  $S_+^{d-1}$ . Based on this model, one can directly work with the MPP  $\Psi = \{(Y_i, B(o, R_i) \cap Z_i)\}_{i \geq 1}$ , with  $M = [0, r] \times G(k, d)$  and  $p = k(d - k)$ . Here, one may be interested in the entropy of some specific characteristics of the grains, for instance their radius  $R$  and direction  $Z$ .

## 2.2 Space of marks

Since our mark space is a manifold, we recall in this section some useful concepts from Riemannian geometry. For further details we refer to [5, 21].

Let  $\mathcal{T}_\eta M$  denote the tangent space of  $M$  at  $\eta \in M$  and let  $\exp_\eta: \mathcal{T}_\eta M \rightarrow M$  denote the exponential map. For any  $r > 0$ ,  $B_M(\eta, r) := \{\nu \in M \mid d_g(\nu, \eta) < r\}$  defines a neighborhood of  $\eta$ , that we call a *normal neighborhood of  $\eta$*  if there exists an open ball  $V \subset \mathcal{T}_\eta M$  such that  $\exp_\eta: V \rightarrow B_M(\eta, r)$  is a diffeomorphism. The *injectivity radius of  $M$*  is defined as  $\text{inj}_g M := \inf_{\eta \in M} \sup\{r \geq 0 \mid B_M(\eta, r) \text{ is a normal nbhd. of } \eta\}$ .

Let  $U$  be a normal neighborhood of  $\eta \in M$  and let  $(U, \psi)$  be the induced exponential chart of  $(M, g)$ . For any  $\nu \in U$ , the *volume density function* introduced by Besse in [4, p.154] is given by

$$\theta_\eta(\nu) := \left| \det \left( g_\nu \left( \frac{\partial}{\partial \psi_i}(\nu), \frac{\partial}{\partial \psi_j}(\nu) \right) \right)_{i,j=1}^p \right|^{1/2},$$

where  $g_\nu(\frac{\partial}{\partial \psi_i}(\nu), \frac{\partial}{\partial \psi_j}(\nu))$  denotes the metric  $g$  in normal coordinates at the point  $\exp_\eta^{-1} \nu$  (see e.g. [21, p.24]). Note that this function is only defined for points  $\nu \in U$  such that  $d_g(\eta, \nu) < \text{inj}_g M$ . Since  $M$  is smooth,  $\theta_\eta$  is continuous on  $M$ .

### 3 Kernel density estimator of the mark distribution

In this section, we introduce a kernel density estimator for the density of the mark distribution on an observation window  $B'_n \subset \mathbb{R}^d$ . More precisely, we consider a sequence  $\{B'_n\}_{n \in \mathbb{N}}$  of bounded Borel sets of  $\mathbb{R}^d$  *growing in the Van Hove sense (VH-growing sequence)*. This means that

$$\lim_{n \rightarrow \infty} |B'_n| = \infty \quad \text{and} \quad \lim_{n \rightarrow \infty} \frac{|\partial B'_n \oplus B(o, r)|}{|B'_n|} = 0,$$

where  $B(o, r)$  denotes the ball of radius  $r > 0$  centered at the origin  $o$ . Given a set  $B \subset \mathbb{R}^d$ ,  $|B|$  will denote its  $d$ -dimensional Lebesgue measure, where  $d$  is the “correct” dimension of  $B$ , i.e. the one for which  $B$  is a  $d$ -set. In this particular case,  $|B'_n|$  is the  $d$ -dimensional volume of  $B'_n$ .

#### 3.1 The estimator

Let  $\Psi = \{(Y_i, \xi_i)\}_{i \geq 1}$  be an homogeneous Poisson marked point process of intensity  $\lambda > 0$ . We define the kernel density estimator

$$\hat{f}_n(\eta) := \frac{1}{\lambda |B'_n|} \sum_{i \geq 1} \frac{\mathbb{1}_{\{Y_i \in B'_n\}}}{b_n^p \theta_\eta(\xi_i)} K \left( \frac{d_g(\eta, \xi_i)}{b_n} \right).$$

This is an extension of the estimator given by Pelletier in [18]. The sequence of bandwidths  $\{b_n\}_{n \in \mathbb{N}} \subset \mathbb{R}$  satisfies

(b1)  $b_n < r_0 \forall n \in \mathbb{N}$ , with  $0 < r_0 < \text{inj}_g M$  and  $\inf_{\eta \in B_M(z, r_0)} \theta_z(\eta) > 0$  for any  $z \in M$ , (b2)  $b_n \downarrow 0$ , (b3)  $\lim_{n \rightarrow \infty} b_n^p |B'_n| = \infty$ .

The kernel  $K: \mathbb{R}_+ \rightarrow \mathbb{R}$  is a bounded nonnegative function satisfying

$$(K1) \text{ supp } K = [0, 1], \quad (K2) \int_{B(o, 1)} K(\|x\|) dx = 1,$$

$$(K3) 0 < \int_{B(o, 1)} K(\|x\|) \|x\|^2 dx =: K_2 < \infty, \quad (K4) \sup_{r \geq 0} K(r) =: K_0 < \infty,$$

$$(K5) \int_{B(o, 1)} K(\|x\|) x dx = o.$$

We further assume that

(f1)  $f \in L^2(M)$ , i.e.  $\|f\|_2^2 := \int_M |f(\eta)|^2 dv_g(\eta) < \infty$ , (f2)  $f$  is twice continuously differentiable. Property (f2) in particular means that  $f$  has bounded Hessian on any normal neighborhood  $U \subset M$ , i.e.  $\exists C_2 > 0$  such that  $\|D^2 f\| \leq C_2$ .

Assumptions on the kernel are standard when dealing with nonparametric density estimation [18, 26]. For the ease of notation, we will usually write

$$F_n(\eta, \xi) := \frac{1}{b_n^p \theta_\eta(\xi)} K\left(\frac{d_g(\eta, \xi)}{b_n}\right), \quad \eta, \xi \in M.$$

In case the observation window  $B'_n$  needs to be explicitly indicated in the notation, we will write  $\hat{f}_{B'_n}$  instead of  $\hat{f}_n$ .

## 3.2 Consistency

In this section, we prove  $L^2$  and almost sure consistency of  $\hat{f}_n$ . In what follows,  $\omega_p$  will denote the volume of the unit ball in  $\mathbb{R}^p$  and we will write  $x \cdot y$  for the Euclidean scalar product of any two vectors  $x, y \in \mathbb{R}^p$ .

Note that in the classical (Euclidean) setting one could shorten proofs by applying Fourier methods [26]. However, in the general case of manifolds, this approach does not seem to be possible.

**Theorem 3.1.** *Under the assumptions (b1) – (b3), (K1) – (K5), (f1) and (f2) we have that*

$$\mathbb{E}[\|\hat{f}_n - f\|_2^2] \leq \frac{C_\theta \omega_p K_0^2}{\lambda |B'_n| b_n^p} + b_n^4 C_2^2 K_2^2 v_g(M),$$

where  $C_\theta := \sup_{z \in M} \sup_{\eta \in B_M(z, r_0)} \theta_z(\eta)^{-1}$ .

**Corollary 3.2.** *Under the above assumptions, it follows directly from Theorem 3.1 that  $\hat{f}_n$  is an  $L^2$ -consistent estimator of  $f$ , i.e.  $\mathbb{E}[\|\hat{f}_n - f\|_2^2] \xrightarrow{n \rightarrow \infty} 0$ .*

**Corollary 3.3.** *Under the assumptions of Theorem 3.1 it holds that*

$$\mathbb{E}[|\hat{f}_n(\xi_0) - f(\xi_0)|^2] \xrightarrow{n \rightarrow \infty} 0.$$

In order to prove these results, we establish some auxiliary lemmata.

**Lemma 3.4.** *For each  $\eta \in M$  and  $n \in \mathbb{N}$ ,*

$$\int_{B_M(\eta, b_n)} \frac{1}{b_n^p \theta_\eta(z)} K\left(\frac{d_g(\eta, z)}{b_n}\right) dv_g(z) = 1. \quad (3.1)$$

*Proof.* Consider the exponential chart  $(U, \psi)$  of  $(M, g)$  introduced in Section 2.2 and set  $z := \exp_\eta(x)$ ,  $B(0, b_n) := \exp_\eta B_M(\eta, b_n)$ . Note that by definition (see [21, p.65] for details) the Jacobian of the transformation  $\|g(x)\|^{1/2}$  coincides with  $\theta_\eta(\exp_\eta(x))$ . The integral in (3.1) thus becomes

$$\int_{B(0, b_n)} \frac{1}{b_n^p \theta_\eta(\exp_\eta(x))} K\left(\frac{\|x\|}{b_n}\right) \|g(x)\|^{1/2} dx = \int_{B(0, 1)} K(\|y\|) dy = 1.$$

□

The calculations in the proof of this lemma lead to the useful equality

$$\int_{B_M(\eta, b_n)} \frac{1}{\theta_\eta(z)} dv_g(z) = \int_{B(0, b_n)} \frac{\|g(x)\|^{1/2}}{\theta_\eta(\exp_\eta(x))} dx = \int_{B(0, b_n)} dx = b_n^p \omega_p. \quad (3.2)$$

We give next an asymptotic bound for the bias of  $\hat{f}_n$ .

**Lemma 3.5.** *For any  $\eta \in \text{supp } f$  and  $n \in \mathbb{N}$*

$$\text{Bias } \hat{f}_n(\eta) := |\mathbb{E}[\hat{f}_n(\eta)] - f(\eta)| \leq b_n^2 C_2 K_2.$$

*Proof.* Let  $\eta \in \text{supp } f$ . By the Campbell theorem,

$$\mathbb{E}[\hat{f}_n(\eta)] = \int_M F_n(\eta, z) f(z) dv_g(z) = \mathbb{E}[F_n(\eta, \xi_0)]. \quad (3.3)$$

Due to Lemma 3.4 and (K2) we have that

$$|\mathbb{E}[F_n(\eta, \xi_0)] - f(\eta)| = \left| \int_{B_M(\eta, b_n)} \frac{1}{b_n^p \theta_\eta(z)} K\left(\frac{d_g(\eta, z)}{b_n}\right) (f(z) - f(\eta)) dv_g(z) \right|.$$

Consider now a normal neighborhood  $\eta \in U \subset M$  and a point  $x = (x^1, \dots, x^p) \in \mathcal{T}_\eta M$  in normal coordinates, i.e.  $z = \exp_\eta(x)$ . Further, define  $\tilde{f} := f \circ \exp_\eta$ . The Taylor expansion of  $f(z)$  around  $\eta$  in normal coordinates is

$$f(z) = \tilde{f}(x) = \tilde{f}(0) + \nabla \tilde{f}(0) \cdot x + R_2(0, x),$$

where  $R_2(0, x) = O(x^T D^2 \tilde{f}(0) x)$  is the second order remainder. From assumption (f2) we have that  $|R_2(0, x)| \leq C_2 \|x\|^2$  for all  $x \in B(0, b_n)$ , hence passing to the exponential chart as in the proof of Lemma 3.4 yields

$$\begin{aligned} & \left| \int_{B_M(\eta, b_n)} \frac{1}{b_n^p \theta_\eta(z)} K\left(\frac{d_g(\eta, z)}{b_n}\right) (f(z) - f(\eta)) dv_g(z) \right| \\ &= \left| \int_{B(0, b_n)} \frac{1}{b_n^p} \frac{1}{\theta_\eta(\exp_\eta(x))} K\left(\frac{\|x\|}{b_n}\right) (\tilde{f}(x) - \tilde{f}(0)) \|g(x)\|^{1/2} dx \right| \end{aligned} \quad (3.4)$$

$$\begin{aligned} &= \left| \int_{B(0, b_n)} \frac{1}{b_n^p} \frac{1}{\theta_\eta(\exp_\eta(x))} K\left(\frac{\|x\|}{b_n}\right) R_2(0, x) \|g(x)\|^{1/2} dx \right| \quad (3.5) \\ &\leq C_2 \int_{B(0, b_n)} \frac{1}{b_n^p} K\left(\frac{\|x\|}{b_n}\right) \|x\|^2 dx = C_2 b_n^2 K_2. \end{aligned}$$

Equality (3.5) follows from (K5) because

$$\begin{aligned} & \int_{B(0, b_n)} \frac{1}{b_n^p} K\left(\frac{\|x\|}{b_n}\right) \nabla \tilde{f}(0) \cdot x dx = \sum_{i=1}^d \int_{B(0, b_n)} \frac{1}{b_n^p} K\left(\frac{\|x\|}{b_n}\right) \nabla \tilde{f}(0)_i x^i dx \\ &= \sum_{i=1}^d \nabla \tilde{f}(0)_i \int_{B(0, b_n)} \frac{1}{b_n^p} K\left(\frac{\|x\|}{b_n}\right) x^i dx = \nabla \tilde{f}(0) \cdot \underbrace{\int_{B(0, b_n)} \frac{1}{b_n^p} K\left(\frac{\|x\|}{b_n}\right) x dx}_{=0} = 0. \end{aligned}$$

□

**Lemma 3.6.** *For any  $n \in \mathbb{N}$ ,*

$$\int_M \mathbb{E}[F_n^2(\eta, \xi_0)] dv_g(\eta) \leq \frac{C_\theta \omega_p K_0^2}{b_n^p},$$

with  $C_\theta$  as in Theorem 3.1.

*Proof.* Applying Fubini's theorem we write

$$\int_M \mathbb{E}[F_n^2(\eta, \xi_0)] dv_g(\eta) = \int_M I(z) f(z) dv_g(z), \quad (3.6)$$

where

$$I(z) = \int_{B_M(z, b_n)} \frac{1}{b_n^{2p} \theta_z^2(\eta)} K^2\left(\frac{d_g(\eta, z)}{b_n}\right) dv_g(\eta).$$

Let us define  $C_\theta(z) := \sup_{\eta \in B_M(z, r_0)} \theta_z(\eta)^{-1}$ , which is finite because of (b1). By assumption (K4) and (3.2),

$$I(z) \leq \frac{C_\theta(z) K_0^2}{b_n^p} \int_{B_M(z, b_n)} \frac{1}{b_n^p \theta_z(\eta)} dv_g(\eta) = \frac{C_\theta(z) \omega_p K_0^2}{b_n^p}.$$

Plugging this estimate into (3.6) finishes the proof. □

We proceed to prove Theorem 3.1.

*Proof of Theorem 3.1.* By Fubini's theorem,

$$\mathbb{E}[\|\hat{f}_n - f\|_2^2] = \int_M \mathbb{E}[|\hat{f}_n(\eta) - f(\eta)|^2] dv_g(\eta) =: \int_M J(\eta) dv_g(\eta).$$

Note that  $J(\eta) = \text{Var}(\hat{f}_n(\eta)) + (\text{Bias } \hat{f}_n(\eta))^2$ . In view of (3.3) and the Campbell theorem we get

$$\begin{aligned} \text{Var}(\hat{f}_n(\eta)) &= \mathbb{E}[\hat{f}_n^2(\eta)] - (\mathbb{E}[\hat{f}_n(\eta)])^2 \\ &= \frac{1}{\lambda^2 |B'_n|^2} \mathbb{E} \left[ \sum_{i \geq 1} \mathbb{1}_{\{Y_i \in B'_n\}} F_n^2(\eta, \xi_i) \right] + \frac{1}{\lambda^2 |B'_n|^2} \mathbb{E} \left[ \sum_{i, j \geq 1}^{\neq} \mathbb{1}_{\{Y_i, Y_j \in B'_n\}} F_n(\eta, \xi_i) F_n(\eta, \xi_j) \right] \\ &\quad - \mathbb{E}[F_n(\eta, \xi_0)]^2 = \frac{1}{\lambda |B'_n|} \mathbb{E}[F_n^2(\eta, \xi_0)] + \frac{\alpha^{(2)}(B'_n \times B'_n)}{\lambda^2 |B'_n|^2} \mathbb{E}[F_n(\eta, \xi_0)]^2 - \mathbb{E}[F_n(\eta, \xi_0)]^2 \\ &= \frac{1}{\lambda |B'_n|} \mathbb{E}[F_n^2(\eta, \xi_0)]. \end{aligned} \tag{3.7}$$

Here,  $\alpha^{(2)}(\cdot)$  denotes the 2nd-order factorial moment measure of the Poisson point process  $\Pi := \{Y_i\}_{i \geq 1}$ . We refer to [25, Chapter 1] for further definitions and formulas related to this measure in the Poisson case. Corollary 3.5 and Lemma 3.6 yield the existence of constants  $C_\theta, C_2 > 0$  such that

$$\mathbb{E}[\|\hat{f}_n - f\|_2^2] \leq \frac{C_\theta \omega_p K_0^2}{\lambda |B'_n| b_n^p} + b_n^4 C_2^2 K_2^2 v_g(M).$$

□

Analogous arguments show the  $L^2$ -convergence of  $\hat{f}_n(\xi_0)$  to  $f(\xi_0)$ .

*Proof of Corollary 3.3.* Passing to normal coordinates as in (3.4) and (3.5) and setting  $\tilde{f} := f \circ \exp_\eta$  lead to

$$\mathbb{E}[F_n(\eta, \xi_0)] = \int_{B(0, b_n)} \frac{1}{b_n^p} K \left( \frac{\|x\|}{b_n} \right) \tilde{f}(x) dx = (1 + o(1)) f(\eta). \tag{3.8}$$

From the proof of Lemma 3.6 we thus obtain

$$\mathbb{E}[F_n^2(\eta, \xi_0)] \leq \frac{K_0 C_\theta(\eta)}{b_n^p} \mathbb{E}[F_n(\eta, \xi_0)] \leq \frac{2K_0 C_\theta(\eta)}{b_n^p} f(\eta) \tag{3.9}$$

for any  $\eta \in \text{supp } f$ . In view of (3.7) and Lemma 3.5, this yields

$$\mathbb{E}[|\hat{f}_n(\xi_0) - f(\xi_0)|^2] \leq \frac{2C_\theta K_0 \|f\|_2^2}{\lambda b_n^p |B'_n|} + b_n^4 C_2^2 K_2^2,$$

which tends to zero as  $n \rightarrow \infty$ .

□

*Remark 3.7.* The problem of finding an optimal sequence of bandwidths  $\{b_n\}_{n \in \mathbb{N}}$  can be understood as a special case of regularization [22] and the bound of the estimation error given in Theorem 3.1 can be used in order to find it. For any fixed  $n \in \mathbb{N}$ , the optimal bandwidth will be  $\operatorname{argmin}_{b_n} \mathbb{E}[\|\hat{f}_n - f\|_2^2]$ . Applying Theorem 3.1, we can approximate the order of magnitude of this optimal  $b_n$  by minimizing the upper bound of the mean square error  $e(b_n) := \frac{C_\theta \omega_p K_0^2}{\lambda |B'_n| b_n^p} + b_n^4 C_2^2 K_2^2 \nu_g(M)$ . A simple calculation leads to the unique minimum point  $b_{n,opt} = \left( \frac{p C_\theta \omega_p K_0^2}{4 C_2^2 K_2^2 \nu_g(M) \lambda |B'_n|} \right)^{\frac{1}{p+4}}$ . Note that  $b_{n,opt} \downarrow 0$  and  $b_{n,opt}^p |B'_n| \rightarrow \infty$  as  $n \rightarrow \infty$ .

We finish this section by proving that if the observation window  $B'_n$  is large enough, then the previous bounds provide the almost surely consistency of  $\hat{f}_n$ .

**Theorem 3.8.** *Under the assumptions of Theorem 3.1, choosing  $b_n = o(n^{-\frac{1+\delta}{4}})$  and  $B'_n$  such that  $b_n^p |B'_n| > n^{1+\delta}$  for some  $\delta > 0$ ,*

$$|\hat{f}_n(\eta) - f(\eta)| \xrightarrow{n \rightarrow \infty} 0 \quad a.s.$$

for any  $\eta \in M$  such that  $f(\eta) < \infty$ .

*Proof.* For each  $\varepsilon > 0$ , Chebyshev's inequality and the bounds used in the proof of Corollary 3.3 yield

$$\mathbb{P}(|\hat{f}_n(\eta) - f(\eta)| > \varepsilon) \leq \frac{\mathbb{E}[|\hat{f}_n(\eta) - f(\eta)|^2]}{\varepsilon^2} \leq \frac{2C_\theta K_0 f(\eta)}{\varepsilon^2 \lambda b_n^p |B'_n|} + \frac{b_n^4 C_2^2 K_2^2}{\varepsilon^2}.$$

Due to the choice of  $b_n$  we have  $b_n^p |B'_n| > n^{1+\delta}$  and  $b_n^4 < n^{-(1+\delta)}$ , hence

$$\sum_{n=1}^{\infty} \mathbb{P}(|\hat{f}_n(\eta) - f(\eta)| > \varepsilon) \leq c_1 f(\eta) \sum_{n=1}^{\infty} \frac{1}{n^{1+\delta}} < \infty$$

for some  $c_1 < \infty$ . The almost sure convergence follows from Borel-Cantelli's lemma.  $\square$

## 4 Entropy estimator

As already mentioned in the introduction, we measure the diversity of the distribution of interest by analyzing its Kolmogorov entropy defined as

$$\mathcal{E}_f := - \int_M f(\eta) \log f(\eta) d\nu_g(\eta),$$

where  $f$  is the density of the distribution. This section is devoted to the construction of a consistent estimator for  $\mathcal{E}_f$ .

## 4.1 Definition of the estimator and consistency

For each  $n \in \mathbb{N}$  we define

$$\widehat{\mathcal{E}}_f(B_n) := -\frac{1}{\lambda|B_n|} \sum_{i \geq 1} \mathbf{1}_{\{Y_i \in B_n\}} \log \hat{f}_{B'_n + Y_i}(\xi_i), \quad (4.1)$$

where  $B'_n + y$  denotes the translation of  $B'_n$  by  $y \in \mathbb{R}^d$  and  $B'_n \subseteq B_n$ . The window  $B'_n$  is introduced for the purpose of notation and it will become relevant when proving the CLT in Section 5. Throughout this section we have no restrictions on it and we can assume  $B_n = B'_n$ .

From now on, we substitute the previous assumption (f1) by  $f$  being continuous. Note that since  $M$  is compact, the new (f1) in particular implies the former. With the additional assumptions for a typical mark  $\xi_0$ ,

$$(L1) \ \mathbb{E} [\log^2 f(\xi_0)] =: L_1 < \infty \quad \text{and} \quad (L2) \ \mathbb{E} \left[ \left( \frac{\|\nabla f(\xi_0)\|}{f(\xi_0)} \right)^2 \right] =: L_2 < \infty,$$

we can prove  $L^2$ -consistency of the estimator.

**Theorem 4.1.** *For each  $n \in \mathbb{N}$ , let  $\{B_n\}_{n \in \mathbb{N}}$  and  $\{B'_n\}_{n \in \mathbb{N}}$  be sequences of VH-growing Borel sets satisfying (b1) – (b3). Further, assume that conditions (K1) – (K5), (f1), (f2), (L1) and (L2) hold. Then,*

$$\mathbb{E}[|\widehat{\mathcal{E}}_f(B_n) - \mathcal{E}_f|^2] \leq 3 \left( \frac{8K_0 C_\theta v_g(M)}{\lambda^2 |B_n| |B'_n| b_n^p} + \frac{4}{\lambda^2 |B'_n|} + 32b_n^2 L_2 + \frac{L_1}{\lambda |B_n|} \right)$$

for sufficiently large  $n \in \mathbb{N}$ .

**Corollary 4.2.** *Under the above assumptions, it follows directly from Theorem 4.1 that  $\widehat{\mathcal{E}}_f(B_n)$  is an  $L^2$ -consistent estimator of  $\mathcal{E}_f$ , i.e.  $\mathbb{E}[|\widehat{\mathcal{E}}_f(B_n) - \mathcal{E}_f|^2] \xrightarrow{n \rightarrow \infty} 0$ .*

## 4.2 Proof of Theorem 4.1

We start by proving the following lemma assuming that all conditions of Theorem 4.1 are satisfied.

**Lemma 4.3.** *For sufficiently large  $n \in \mathbb{N}$  it holds that*

$$\int_{\text{supp } f} \frac{(\mathbb{E}[\hat{f}_{B'_n}(\eta)] - f(\eta))^2}{f(\eta)} dv_g(\eta) \leq 4b_n^2 L_2.$$

*Proof.* Recall from (3.3) that  $\mathbb{E}[\hat{f}_{B'_n}(\eta)] = \mathbb{E}[F_n(\eta, \xi_0)]$ . Using normal coordinates analogously to (3.4) and (3.5) with  $\tilde{f} := f \circ \exp_\eta$  we obtain

$$\begin{aligned} |\mathbb{E}[F_n(\eta, \xi_0)] - f(\eta)| &= \left| \int_{B(0, b_n)} \frac{1}{b_n^p} K\left(\frac{\|x\|}{b_n}\right) x \cdot \int_0^1 \nabla \tilde{f}(tx) dt dx \right| \\ &\leq b_n \int_{B(0, 1)} K(\|y\|) \|y\| \int_0^1 \|\nabla \tilde{f}(tb_n y)\| dt dy. \end{aligned}$$

Since  $b_n \downarrow 0$ , we have  $\|\nabla \tilde{f}(tb_n y)\| = \|\nabla \tilde{f}(0)\|(1 + o(1))$  for sufficiently large  $n \in \mathbb{N}$  and in view of (K2), last expression can be bounded by

$$2b_n \|\nabla \tilde{f}(0)\| \int_{B(0, 1)} K(\|y\|) \|y\| dy \leq 2b_n \|\nabla \tilde{f}(0)\|.$$

Hence,  $|\mathbb{E}[\hat{f}_{B'_n}(\eta)] - f(\eta)| \leq 2b_n \|\nabla f(\eta)\|$  for sufficiently large  $n \in \mathbb{N}$  and (L2) yields

$$\int_{\text{supp } f} \frac{(\mathbb{E}[\hat{f}_{B'_n}(\eta)] - f(\eta))^2}{f(\eta)} dv_g(\eta) \leq 4b_n^2 \int_{\text{supp } f} \frac{\|\nabla f(\eta)\|^2}{f(\eta)} dv_g(\eta) = 4b_n^2 L_2.$$

□

We now proceed to prove Theorem 4.1. Based on [1], we introduce the quantities

$$\begin{aligned} L_n &:= -\frac{1}{\lambda|B_n|} \sum_{i \geq 1} \mathbb{1}_{\{Y_i \in B_n\}} \log \mathbb{E}[\hat{f}_{B'_n + Y_i}(\xi_i)], \\ M_n &:= -\frac{1}{\lambda|B_n|} \sum_{i \geq 1} \mathbb{1}_{\{Y_i \in B_n\}} \log f(\xi_i). \end{aligned}$$

Applying inequality  $(a + b + c)^2 \leq 3(a^2 + b^2 + c^2)$ ,  $a, b, c \in \mathbb{R}$ , leads to

$$\mathbb{E}[|\hat{\mathcal{E}}_f(B_n) - \mathcal{E}_f|^2] \leq 3 \left( \underbrace{\mathbb{E}[\hat{\mathcal{E}}_f(B_n) - L_n]^2}_{=: I_{1,n}} + \underbrace{\mathbb{E}[L_n - M_n]^2}_{=: I_{2,n}} + \underbrace{\mathbb{E}[M_n - \mathcal{E}_f]^2}_{=: I_{3,n}} \right),$$

hence our aim is to compute an upper bound for  $I_{i,n}$  and each  $i = 1, 2, 3$ . First,

$$\begin{aligned} I_{1,n} &= \frac{1}{\lambda^2 |B_n|^2} \mathbb{E} \left[ \sum_{i \geq 1} \mathbb{1}_{\{Y_i \in B_n\}} (\log \hat{f}_{B'_n + Y_i}(\xi_i) - \log \mathbb{E}[\hat{f}_{B'_n + Y_i}(\xi_i)])^2 \right] \\ &\quad + \frac{1}{\lambda^2 |B_n|^2} \mathbb{E} \left[ \sum_{i, j \geq 1}^{\neq} \mathbb{1}_{\{Y_i, Y_j \in B_n\}} (\log \hat{f}_{B'_n + Y_i}(\xi_i) - \log \mathbb{E}[\hat{f}_{B'_n + Y_i}(\xi_i)]) \times \right. \\ &\quad \left. \times (\log \hat{f}_{B'_n + Y_j}(\xi_j) - \log \mathbb{E}[\hat{f}_{B'_n + Y_j}(\xi_j)]) \right] =: J_1 + J_2. \end{aligned}$$

On the one hand, notice that by definition,

$$h(Y_i, \xi_i, T_{Y_i} \Psi - \delta_{(o, \xi_i)}) := \mathbb{1}_{\{Y_i \in B_n\}} (\log \hat{f}_{B'_n + Y_i}(\xi_i) - \log \mathbb{E}[\hat{f}_{B'_n + Y_i}(\xi_i)])^2$$

depends on  $(Y_i, \xi_i)$  and  $T_{Y_i}\Psi - \delta_{(o, \xi_i)}$ . Since  $\Psi$  is an independently marked Poisson MPP, the Campbell-Mecke type formula in [24, p.129] yields

$$\frac{1}{\lambda^2|B_n|^2}\mathbb{E}\left[\sum_{i \geq 1} h(Y_i, \xi_i, T_{Y_i}\Psi - \delta_{(o, \xi_i)})\right] = \frac{1}{\lambda|B_n|^2} \int_{\mathbb{R}^d} \int_M \mathbb{E}_{P_{\eta}^!}[h(y, \eta, \Psi)]f(\eta)dv_g(\eta)dy,$$

where  $\mathbb{E}_{P_{(o, \eta)}^!}$  denotes expectation with respect to the reduced Palm distribution of  $\Psi$ . Again because  $\Psi$  is an independently marked Poisson MPP,  $P_{(o, \eta)}^!$  coincides with the distribution of  $\Psi$  and we obtain

$$J_1 = \frac{1}{\lambda|B_n|^2} \int_{B_n} \int_M \mathbb{E}[(\log \hat{f}_{B'_n+y}(\eta) - \log \mathbb{E}[\hat{f}_{B'_n+y}(\eta)])^2]f(\eta)dv_g(\eta)dy.$$

Notice that  $\log x$  is a differentiable function, hence the mean value theorem yields

$$|\log x - \log z| = \frac{|x - z|}{|(1 - \gamma)x + \gamma z|} \leq \frac{|x - z|}{\min\{x, z\}}, \quad x, z > 0 \quad (4.2)$$

for some  $\gamma \in (0, 1)$ . Since  $\Psi$  is stationary and by assumption (f1)  $f$  is continuous,  $\hat{f}_{B'_n+y}(\eta)$  converges to  $f(\eta)$  a.s. for any  $y \in \mathbb{R}^d$  and  $\eta \in M$  by Theorem 3.8. Furthermore, in view of (3.8),  $\mathbb{E}[F_n(\eta, \xi_0)] = (1 + o(1))f(\eta)$ , hence for  $n \in \mathbb{N}$  large enough

$$\min\{\hat{f}_{B'_n+y}(\eta), \mathbb{E}[\hat{f}_{B'_n+y}(\eta)]\} \geq \frac{1}{2}f(\eta). \quad (4.3)$$

Applying inequality (4.2) with  $x = \hat{f}_{B'_n+y}(\eta)$  and  $z = \mathbb{E}[\hat{f}_{B'_n+y}(\eta)] = \mathbb{E}[F_n(\eta, \xi_0)]$  we obtain

$$J_1 \leq \frac{4}{\lambda|B_n|^2} \int_{B_n} \int_M \frac{\mathbb{E}[(\hat{f}_{B'_n+y}(\eta) - \mathbb{E}[\hat{f}_{B'_n+y}(\eta)])^2]}{f(\eta)^2} f(\eta)dv_g(\eta)dy.$$

Due to (3.7) and (3.9),

$$J_1 \leq \frac{4}{\lambda|B_n|} \int_M \frac{\mathbb{E}[F_n^2(\eta, \xi_0)]}{f(\eta)^2 \lambda|B'_n|} f(\eta)dv_g(\eta)dy \leq \frac{8K_0 C_\theta v_g(M)}{\lambda^2|B_n||B'_n|b_n^p}. \quad (4.4)$$

Analogously, each summand in  $J_2$  can be expressed as a function  $h$  depending of  $(Y_i, \xi_i)$ ,  $(Y_j, \xi_j)$  and  $T_{Y_i}\Psi - \delta_{(o, \xi_i)} - \delta_{(Y_j, \xi_j)}$ . Hence, the Campbell-Mecke type formula in [24, p.129] in the independently marked Poisson case yields

$$\begin{aligned} J_2 &= \mathbb{E}\left[\sum_{i, j \geq 1}^{\neq} h(Y_i, \xi_i, Y_j, \xi_j, T_{Y_i}\Psi - \delta_{(o, \xi_i)} - \delta_{(Y_j, \xi_j)})\right] \\ &= \lambda \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \int_{M^2} \mathbb{E}_{P_{\eta_1, \eta_2}^{o, y_2}!}[h(y_1, \eta_1, y_2, \eta_2, \Psi)]f(\eta_1)f(\eta_2)dv_g(\eta_2)dv_g(\eta_1)dy_1 dy_2 \\ &= \lambda \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \int_{M^2} \mathbb{E}[h(y_1, \eta_1, y_2, \eta_2, \Psi)]f(\eta_1)f(\eta_2)dv_g(\eta_2)dv_g(\eta_1)dy_1 dy_2, \end{aligned}$$

where last inequality follows from the independent marking of the Poisson MPP. Applying again Theorem 3.8, (4.2) and (3.8), we obtain for  $n \in \mathbb{N}$  large enough

$$J_2 \leq \frac{4}{\lambda|B_n|^2} \int_{(B_n \times M)^2} \frac{\text{Cov}(\hat{f}_{B'_n+y_1}(\eta_1), \hat{f}_{B'_n+y_2}(\eta_2))}{f(\eta_1)f(\eta_2)} f(\eta_1)f(\eta_2) dv_g(\eta_2)dv_g(\eta_1)dy_1 dy_2.$$

In view of (3.3) and the Campbell theorem,

$$\begin{aligned} \text{Cov}(\hat{f}_{B'_n+y_1}(\eta_1), \hat{f}_{B'_n+y_2}(\eta_2)) &= \mathbb{E}[\hat{f}_{B'_n+y_1}(\eta_1)\hat{f}_{B'_n+y_2}(\eta_2)] - \mathbb{E}[\hat{f}_{B'_n+y_1}(\eta_1)]\mathbb{E}[\hat{f}_{B'_n+y_2}(\eta_2)] \\ &= \frac{1}{\lambda^2|B'_n|^2} \mathbb{E}\left[\sum_{i \geq 1} \mathbb{1}_{\{Y_i \in (B'_n+y_1) \cap (B'_n+y_2)\}} F_n(\eta_1, \xi_i) F_n(\eta_2, \xi_i)\right] \\ &\quad + \frac{1}{\lambda^2|B'_n|^2} \mathbb{E}\left[\sum_{i,j \geq 1}^{\neq} \mathbb{1}_{\{Y_i \in B'_n+y_1\}} \mathbb{1}_{\{Y_j \in B'_n+y_2\}} F_n(\eta_1, \xi_i) F_n(\eta_2, \xi_j)\right] \\ &\quad - \mathbb{E}[F_n(\eta_1, \xi_0)]\mathbb{E}[F_n(\eta_2, \xi_0)] \\ &= \frac{|(B'_n+y_1) \cap (B'_n+y_2)|}{\lambda|B'_n|^2} \mathbb{E}[F_n(\eta_1, \xi_0)F_n(\eta_2, \xi_0)] \leq \frac{1}{\lambda|B'_n|} \mathbb{E}[F_n(\eta_1, \xi_0)F_n(\eta_2, \xi_0)]. \end{aligned}$$

Fubini's theorem and Lemma 3.4 yield

$$J_2 \leq \frac{4}{\lambda^2|B'_n|} \int_{M^2} \mathbb{E}[F_n(\eta_1, \xi_0)F_n(\eta_2, \xi_0)] dv_g(\eta_1)dv_g(\eta_2) = \frac{4}{\lambda^2|B'_n|},$$

which together with (4.4) leads to  $I_{1,n} \leq \frac{8K_0 C_\theta v_g(M)}{\lambda^2|B_n||B'_n|b_n^2} + \frac{4}{\lambda^2|B'_n|}$ . Secondly, due to the stationarity of  $\Psi$  and the Campbell theorem we have for large  $n \in \mathbb{N}$

$$\begin{aligned} I_{2,n} &= \frac{1}{\lambda^2|B_n|^2} \mathbb{E}\left[\sum_{i \geq 1} \mathbb{1}_{\{Y_i \in B_n\}} (\log \mathbb{E}[\hat{f}_{B'_n+Y_i}(\xi_i)] - \log f(\xi_i))^2\right] \\ &\quad + \frac{1}{\lambda^2|B_n|^2} \mathbb{E}\left[\sum_{i,j \geq 1}^{\neq} \mathbb{1}_{\{Y_i, Y_j \in B_n\}} (\log \mathbb{E}[\hat{f}_{B'_n+Y_i}(\xi_i)] - \log f(\xi_i))(\log \mathbb{E}[\hat{f}_{B'_n+Y_j}(\xi_j)] - \log f(\xi_j))\right] \\ &= \frac{1}{\lambda|B_n|} \mathbb{E}[(\log \mathbb{E}[\hat{f}_{B'_n}(\xi_0)] - \log f(\xi_0))^2] + (\mathbb{E}[\log \mathbb{E}[\hat{f}_{B'_n}(\xi_0)] - \log f(\xi_0)])^2 \\ &\leq 2\mathbb{E}[(\log \mathbb{E}[\hat{f}_{B'_n}(\xi_0)] - \log f(\xi_0))^2]. \end{aligned}$$

On the other hand, by (4.3) and Lemma 4.3 we get

$$\mathbb{E}[(\log \mathbb{E}[\hat{f}_{B'_n}(\xi_0)] - \log f(\xi_0))^2] \leq 4 \int_{\text{supp } f} \frac{(\mathbb{E}[\hat{f}_{B'_n}(\eta)] - f(\eta))^2}{f(\eta)} dv(\eta) \leq 16b_n^2 L_2,$$

so that  $I_{2,n} \leq 32b_n^2 L_2$ .

Finally, note that  $\mathcal{E}_f = -\mathbb{E}[\log f(\xi_0)]$ . Applying once again the Campbell theorem we

obtain

$$\begin{aligned}
I_{3,n} &= \frac{1}{\lambda^2 |B_n|^2} \left( \mathbb{E} \left[ \sum_{i \geq 1} \mathbb{1}_{\{Y_i \in B_n\}} \log^2 f(\xi_i) \right] + \mathbb{E} \left[ \sum_{i,j \geq 1}^{\neq} \mathbb{1}_{\{Y_i, Y_j \in B_n\}} \log f(\xi_i) \log f(\xi_j) \right] \right) \\
&\quad + \frac{2}{\lambda |B_n|} \mathbb{E} \left[ \sum_{i \geq 1} \mathbb{1}_{\{Y_i \in B_n\}} \log f(\xi_i) \right] \mathcal{E}_f + \mathcal{E}_f^2 \\
&= \frac{1}{\lambda |B_n|} \mathbb{E} [\log^2 f(\xi_0)] + (\mathbb{E} [\log f(\xi_0)])^2 + 2 \mathbb{E} [\log f(\xi_0)] \mathcal{E}_f + \mathcal{E}_f^2 \\
&= \frac{1}{\lambda |B_n|} \mathbb{E} [\log^2 f(\xi_0)] = \frac{L_1}{\lambda |B_n|}.
\end{aligned}$$

*Remark 4.4.* The proof of Theorem 4.1 gives an explicit bound of the error that can be used to find an optimal sequence of bandwidths. In this case analogous calculations to Remark 3.7 lead to  $b_{n,opt} = \left( \frac{pK_0 C_\theta v_g(M)}{4L_2 \lambda^2 |B_n| |B'_n|} \right)^{\frac{1}{p+2}}$ .

## 5 Central limit theorem for entropy

If the window  $B'_n$  satisfies that  $B'_n \subset B_n$ , and  $m_n$  is the diameter of  $B'_n$ , the estimator  $\widehat{\mathcal{E}}_f(B_n)$  can be seen as a normalized random sum of elements of a stationary  $m_n$ -dependent random field. In this section, we present a CLT for a modified version of the original estimator.

Let us start by fixing some notation. In general, we use uppercase for coordinates and lowercase for enumerating elements. For  $\mathbb{K} \in \{\mathbb{N}, \mathbb{Z}, \mathbb{R}\}$ , any  $j \in \mathbb{K}^d$  will therefore be written as  $j = (j^1, \dots, j^d)$ , while  $j_1, j_2, \dots$  will denote a sequence in  $\mathbb{K}^d$ . Moreover, we write  $\mathbf{t} = (t, \dots, t) \in \mathbb{K}^d$  for any  $t \in \mathbb{K}$ . We set  $C_y := \times_{k=1}^d [0, y^k)$  for any  $y \in \mathbb{R}_+^d$  and  $V_j := C_j \cap \mathbb{N}^d$  for  $j \in \mathbb{N}^d$ . In particular,  $C_{\mathbf{t}} = [0, t)^d$  for  $t \in \mathbb{R}_+$ .

A random field  $\{X_j, j \in \mathbb{K}^d\}$  is said to be  $m$ -dependent for some  $m > 0$  if for any finite sets  $I, J \subset \mathbb{K}^d$  the random vectors  $(X_i)_{i \in I}$  and  $(X_j)_{j \in J}$  are independent whenever  $\|i - j\|_\infty > m$  for all  $i \in I$  and  $j \in J$ .

In stochastic geometry,  $m$ -dependent random fields often appear in connection with models based on independently marked point processes. A CLT for sums of  $m$ -dependent random fields was first investigated by Rosén [19] and improved by Heinrich [11]. These results have been extended in the last years to weaker dependence structures (see [8, 24] and references therein).

### 5.1 Theoretical results

Our CLT is based on the following result by Chen and Shao [8] for deterministic sums of  $m$ -dependent random fields.

**Theorem 5.1.** [8, Theorem 2.6] Let  $\{X_i\}_{i \in I}$ ,  $I \subseteq \mathbb{N}^d$ , be a centered  $m$ -dependent random field such that  $\mathbb{E}[|X_i|^q] < \infty$  for some  $2 < q \leq 3$  and any  $i \in I$ . Then,

$$\sup_{x \in \mathbb{R}} |F(x) - \Phi(x)| \leq 75(10m + 1)^{(q-1)d} \left( \text{Var} \sum_{i \in I} X_i \right)^{-q/2} \sum_{i \in I} \mathbb{E}[|X_i|^q],$$

where  $F$  is the distribution function of  $(\text{Var} \sum_{i \in I} X_i)^{-1/2} \sum_{i \in I} X_i$ .

We give an extension of this theorem to random sums of stationary  $m_n$ -dependent random fields indexed in  $\mathbb{R}_+^d$ . For simplicity, we assume that our observation windows are cubic, i.e.  $B_n := C_{\mathbf{p}_n}$  with  $p_n \rightarrow \infty$  as  $n \rightarrow \infty$ .

**Corollary 5.2.** Let  $\{X_{n,y}, y \in B_n\}_{n \in \mathbb{N}}$  be a sequence of stationary centered  $m_n$ -dependent random fields and let  $\Pi$  be a stationary Poisson point process on  $\mathbb{R}_+^d$ . Assume that

$$\sup_{n \in \mathbb{N}} \mathbb{E} \left[ \left| \sum_{y \in \Pi \cap C_1} X_{n,y} \right|^q \right] < \infty \quad (\text{A})$$

for some  $2 < q \leq 3$ . Then,

$$\sup_{x \in \mathbb{R}} |F_n(x) - \Phi(x)| \leq 75(10m_n + 11)^{(q-1)d} |B_n| \sigma_n^{-q} \mathbb{E} \left[ \left| \sum_{y \in \Pi \cap C_1} X_{n,y} \right|^q \right],$$

where  $\sigma_n^2 = \text{Var} \sum_{y \in \Pi \cap B_n} X_{n,y}$  and  $F_n$  is the distribution function of  $\sum_{y \in \Pi \cap B_n} X_{n,y} / \sigma_n$ .

*Proof.* For each  $j \in \mathbb{N}^d$  and  $n \in \mathbb{N}$ , define  $Z_{n,j} := \sum_{y \in \Pi \cap (C_1 + j)} X_{n,y}$ . Obviously,  $\{Z_{n,j}\}_{j \in V_{\mathbf{p}_n}}$  is a stationary centered  $(m_n + 1)$ -dependent random field with  $\sup_{n \in \mathbb{N}} \mathbb{E}[|Z_{n,j}|^q] < \infty$  for any  $j \in V_{\mathbf{p}_n}$  and  $2 < q \leq 3$ . Hence, Theorem 5.1 with  $I = V_{\mathbf{p}_n}$  yields the stated bound.  $\square$

*Remark 5.3.* Note that Corollary 5.2 does not require independence between the random fields  $\{X_{n,y}\}_{y \in B_n}$  and the point process  $\Pi$ . If independence is provided, the Campbell theorem together with the generalized Cauchy-Schwartz inequality and the stationarity of  $\Pi$  lead to

$$\begin{aligned} \mathbb{E} \left[ \left| \sum_{y \in \Pi \cap C_1} X_{n,y} \right|^3 \right] &\leq \lambda \int_{C_1} \mathbb{E}[|X_{n,y}|^3] dy + \lambda \int_{C_1^2} \mathbb{E}[X_{n,y_1}^2 |X_{n,y_2}|] \alpha^{(2)}(dy_1, dy_2) \\ &+ \lambda \int_{C_1^3} \mathbb{E}[|X_{n,y_1} X_{n,y_2} X_{n,y_3}|] \alpha^{(3)}(dy_1, dy_2, dy_3) \\ &\leq \lambda \mathbb{E}[|X_{n,\mathbf{0}}|^3] (1 + \alpha^{(2)}(C_1^2) + \alpha^{(3)}(C_1^3)) = \lambda \mathbb{E}[|X_{n,\mathbf{0}}|^3] (1 + \lambda^2 + \lambda^3), \end{aligned}$$

where  $\lambda > 0$  is the intensity of  $\Pi$  and  $\alpha^{(k)}$ ,  $k = 2, 3$ , denotes the  $k$ -th order factorial moment measure of  $\Pi$  (see [25, Chapter 1] for explicit formulas in the Poisson case). Thus, we may substitute condition (A) by

$$\sup_{n \in \mathbb{N}} \mathbb{E}[|X_{n,\mathbf{0}}|^3] < \infty \quad (\text{A}')$$

and obtain Corollary 5.2 in the case  $q = 3$ .

Before applying Corollary 5.2 and Remark 5.3 to our entropy estimator, we want to investigate under which conditions the limiting variance exists. The following theorem is an extension of [6, Theorem 1.8, p.175] to random sums of wide-sense stationary random fields indexed in  $\mathbb{R}^d$ .

**Theorem 5.4.** *Let  $\{X_{n,y}, y \in \mathbb{R}^d\}_{n \in \mathbb{N}}$  be a sequence of wide-sense stationary measurable centered random fields and let  $\Pi$  be a homogeneous Poisson point process of intensity  $\lambda > 0$  independent of  $\{X_{n,y}, y \in \mathbb{R}^d\}$ . Assume that*

$$\lim_{p \rightarrow \infty} \limsup_{n \rightarrow \infty} \int_{\mathbb{R}^d \setminus (-p,p)^d} |\text{Cov}(X_{n,\mathbf{0}}, X_{n,y})| dy = 0, \quad (5.1)$$

and

$$\sup_{n \in \mathbb{N}} \int_{\mathbb{R}^d} |\text{Cov}(X_{n,\mathbf{0}}, X_{n,y})| dy < \infty. \quad (5.2)$$

If the limit

$$\sigma^2 := \lim_{n \rightarrow \infty} \left( \lambda \mathbb{E}[X_{n,\mathbf{0}}^2] + \lambda^2 \int_{\mathbb{R}^d} \text{Cov}(X_{n,\mathbf{0}}, X_{n,y}) dy \right)$$

exists and is positive, then

$$\frac{1}{|U_n|} \text{Var} \left( \sum_{y \in \Pi \cap U_n} X_{n,y} \right) \xrightarrow{n \rightarrow \infty} \sigma^2 \quad (5.3)$$

for any VH-growing sequence  $\{U_n\}_{n \in \mathbb{N}} \subseteq \mathbb{R}^d$ .

*Proof.* Since  $\Pi$  is a Poisson point process independent of  $\{X_{n,y}\}_{y \in \mathbb{R}^d}$ , it follows from the Campbell theorem and the wide-sense stationarity that

$$\begin{aligned} \text{Var} \left( \sum_{y \in \Pi \cap U_n} X_{n,y} \right) &= \lambda |U_n| \mathbb{E}[X_{n,\mathbf{0}}^2] + \lambda^2 |U_n| \int_{\mathbb{R}^d} \text{Cov}(X_{n,\mathbf{0}}, X_{n,y}) dy \\ &\quad - \lambda^2 \int_{U_n} \int_{U_n^c} \text{Cov}(X_{n,y_1}, X_{n,y_2}) dy_1 dy_2. \end{aligned}$$

Following the proof of [6, Theorem 1.8], let  $p > 0$  be arbitrary and set  $G_n := U_n \cap (\partial U_n)_p$ ,  $W_n := U_n \setminus G_n$ , where  $(\partial U_n)_p := \partial U_n \oplus B(\mathbf{0}, p)$  denotes the  $p$ -neighborhood of  $\partial U_n \subset \mathbb{R}^d$ . From the previous calculation we have

$$\begin{aligned} &\lambda |U_n| \mathbb{E}[X_{n,\mathbf{0}}^2] + \lambda^2 |U_n| \int_{\mathbb{R}^d} \text{Cov}(X_{n,\mathbf{0}}, X_{n,y}) dy - \text{Var} \left( \sum_{y \in \Pi \cap U_n} X_{n,y} \right) \\ &= \lambda^2 \int_{G_n} \int_{U_n^c} \text{Cov}(X_{n,y_1}, X_{n,y_2}) dy_1 dy_2 + \lambda^2 \int_{W_n} \int_{U_n^c} \text{Cov}(X_{n,y_1}, X_{n,y_2}) dy_1 dy_2 \\ &=: R_{n,1} + R_{n,2}. \end{aligned}$$

On the one hand,  $|G_n| \leq |(\partial U_n)_p|$  and since  $\{U_n\}_{n \in \mathbb{N}}$  is VH-growing, assumption (5.2) yields

$$\frac{|R_{n,1}|}{|U_n|} \leq \frac{|(\partial U_n)_p|}{|U_n|} \lambda^2 \int_{\mathbb{R}^d} |\text{Cov}(X_{n,\mathbf{0}}, X_{n,y})| dy \xrightarrow{n \rightarrow \infty} 0.$$

On the other hand,  $\text{dist}(W_n, U_n^c) \geq p$  and  $|W_n| \leq |U_n|$ , hence

$$\frac{|R_{n,2}|}{|U_n|} \leq \frac{|W_n|}{|U_n|} \lambda^2 \int_{\mathbb{R}^d \setminus (-p,p)^d} |\text{Cov}(X_{n,\mathbf{0}}, X_{n,y})| dy \leq \lambda^2 \int_{\mathbb{R}^d \setminus (-p,p)^d} |\text{Cov}(X_{n,\mathbf{0}}, X_{n,y})| dy$$

and in view of assumption (5.1) the convergence in (5.3) is established.  $\square$

The same holds under weaker assumptions if the random fields  $\{X_{n,y}, y \in \mathbb{R}^d\}_{n \in \mathbb{N}}$  are  $m_n$ -dependent.

**Corollary 5.5.** *Let  $\{X_{n,y}, y \in \mathbb{R}^d\}_{n \in \mathbb{N}}$  be a sequence of wide-sense stationary measurable centered  $m_n$ -dependent random fields and let  $\Pi$  be a homogeneous Poisson point process of intensity  $\lambda > 0$  independent of  $\{X_{n,y}, y \in \mathbb{R}^d\}_{n \in \mathbb{N}}$ . Assume that*

$$\sup_{n \in \mathbb{N}} \int_{\mathbb{R}^d} |\text{Cov}(X_{n,\mathbf{0}}, X_{n,y})| dy < \infty. \quad (5.4)$$

*If the limit*

$$\sigma^2 := \lim_{n \rightarrow \infty} \left( \lambda \mathbb{E}[X_{n,\mathbf{0}}^2] + \lambda^2 \int_{\mathbb{R}^d} \text{Cov}(X_{n,\mathbf{0}}, X_{n,y}) dy \right)$$

*exists and is positive, then*

$$\lim_{n \rightarrow \infty} \frac{1}{|U_n|} \text{Var} \left( \sum_{y \in \Pi \cap U_n} X_{n,y} \right) \xrightarrow{n \rightarrow \infty} \sigma^2$$

*for any sequence of subsets  $\{U_n\}_{n \in \mathbb{N}}$  satisfying  $\frac{|(\partial U_n)_{m_n}|}{|U_n|} \xrightarrow{n \rightarrow \infty} 0$ .*

*Remark 5.6.* The result holds for instance by taking cubic windows  $U_n = C_{\mathbf{u}_n}$  with  $\frac{m_n}{u_n} \xrightarrow{n \rightarrow \infty} 0$ .

*Proof.* Set  $p = m_n$  in the proof of Theorem 5.4. Due to  $m_n$ -dependence, condition (5.1) is trivially fulfilled and therefore  $\limsup_{n \rightarrow \infty} \frac{|R_{n,2}|}{|U_n|} = 0$ . On the other hand,

$$\frac{|R_{n,1}|}{|U_n|} \leq \frac{|(\partial U_n)_{m_n}|}{|U_n|} \int_{\mathbb{R}^d} |\text{Cov}(X_{n,\mathbf{0}}, X_{n,y})| dy \xrightarrow{n \rightarrow \infty} 0$$

in view of assumption (5.4) and the choice of  $U_n$ .  $\square$

## 5.2 Application to entropy

The results of last paragraph evince that the independence between the Poisson point process  $\Pi$  and the sequence  $\{X_{n,y}, y \in \mathbb{R}_+^d\}_{n \in \mathbb{N}}$  is crucial to perform calculations. Therefore, we need to consider the modified estimator

$$\hat{\mathcal{E}}_f^*(B_n) := -\frac{1}{\lambda|B_n|} \sum_{i \geq 1} \mathbb{1}_{\{Y_i^* \in B_n\}} \log \hat{f}_{B_n' + y}(\xi_i^*),$$

where  $\Psi^* := \{(Y_i^*, \xi_i^*)\}_{i \geq 1}$  is an independent copy of the original Poisson MPP  $\Psi$ . The study of the original estimator is subject of further research and it involves MPPs whose marks depend of their location (we refer to [17, 13, 12] for some investigations in this direction). Moreover, we also need to assume

$$(f3) \inf_{\eta \in \text{supp } f} f(\eta) := c_0 > 0.$$

This assumption, although being very restrictive, is usual in the context of entropy estimation (see e.g. [3]). We could substitute it by a set of slightly milder yet cumbersome assumptions and opted for the former for ease of proofs. The aim of this section is to apply Corollary 5.2 in order to obtain a CLT for  $\hat{\mathcal{E}}_f^*(B_n)$ .

**Theorem 5.7.** *Let  $\{B_n\}_{n \in \mathbb{N}}$  and  $\{B_n'\}_{n \in \mathbb{N}}$  be sequences of observation windows in  $\mathbb{R}_+^d$  with  $B_n = C_{\mathbf{p}_n}$ ,  $B_n' = C_{\mathbf{m}_n}$  for some  $p_n, m_n > 0$ . Under the conditions of Theorem 4.1, there exists a  $a > 0$  such that for any  $n \in \mathbb{N}$ ,*

$$\sup_{x \in \mathbb{R}} |F_n(x) - \Phi(x)| \leq \frac{600a\lambda(1 + \lambda^2 + \lambda^3)(10|B_n'|^{1/d} + 11)^{2d}}{|B_n|^{1/2}}, \quad (5.5)$$

where  $F_n$  is the distribution function of

$$\sqrt{|B_n|} \frac{\hat{\mathcal{E}}_f^*(B_n) - \hat{\mu}_{B_n}}{\sigma_n}$$

with

$$\hat{\mu}_{B_n} := -\frac{\Pi^*(B_n)}{\lambda|B_n|} \mathbb{E}[\log \hat{f}_{B_n'}(\xi_0)]$$

and

$$\sigma_n^2 := \lambda \text{Var}(\log \hat{f}_{B_n'}(\xi_0)) + \lambda^2 \int_{B_n'} \text{Cov}(\log \hat{f}_{B_n'}(\xi_0), \log \hat{f}_{B_n'}(\xi'_y)) dy,$$

where  $\{\xi'_y\}_{y \in \mathbb{R}_+^d}$  are independent copies of  $\xi_0$ .

Choosing a suitable size relation between  $B_n$  and  $B_n'$  leads to the desired CLT.

**Corollary 5.8.** *If the side-lengths of the observation windows satisfy  $p_n = m_n^{4+\delta}$  for some  $\delta > 0$  and any  $n \in \mathbb{N}$ , then*

$$\sqrt{|B_n|} \frac{\hat{\mathcal{E}}_f^*(B_n) - \hat{\mu}_{B_n}}{\sigma_n} \xrightarrow[n \rightarrow \infty]{d} \mathcal{N}(0, 1)$$

with the uniform rate of convergence of order  $m_n^{-\delta d/2}$  given in (5.5).

### 5.3 Proof of Theorem 5.7

First of all, notice that

$$\sqrt{|B_n|} \frac{\hat{\mathcal{E}}_f^*(B_n) - \hat{\mu}_{B_n}}{\sigma_n} =: \sum_{y \in \Pi^* \cap B_n} X_{n,y},$$

where  $X_{n,y} = \frac{1}{\sqrt{|B_n|\sigma_n}} (-\log \hat{f}_{B'_n+y}(\xi_y^*) + \mathbb{E}[\log \hat{f}_{B'_n}(\xi_0)])$  is a stationary centered  $m_n$ -dependent random field with variance one. Our strategy will thus consist in verifying condition (A') and computing the bound given by Corollary 5.2. In order to do so we prove next some helpful lemmata.

For the ease of reading, we use the notation  $\hat{f}_{B'_n+y}$  instead of  $\hat{f}_{B'_n+y}(\xi_y')$  and only refer explicitly to the argument when confusion may occur. Moreover, we assume that the conditions of Theorem 5.7 hold in the subsequent lemmata without mentioning them explicitly.

Let us begin by proving the uniform boundedness of the third moment.

**Lemma 5.9.** *There exists a constant  $c_1 > 0$  such that for any  $y \in \mathbb{R}_+^d$  and  $n \in \mathbb{N}$*

$$\mathbb{E}[|\log \hat{f}_{B'_n+y}|^3] \leq c_1.$$

*Proof.* Due to stationarity, it suffices to show that the assertion holds for  $\mathbb{E}[|\log \hat{f}_{B'_n}|^3]$ . On the one hand, by adding and subtracting  $\log \mathbb{E}[\hat{f}_{B'_n}]$  we have

$$\begin{aligned} \mathbb{E}[|\log \hat{f}_{B'_n}|^3] &\leq \mathbb{E}[|\log \hat{f}_{B'_n} - \log \mathbb{E}[\hat{f}_{B'_n}]|^3] + 3 |\log \mathbb{E}[\hat{f}_{B'_n}]| \mathbb{E}[|\log \hat{f}_{B'_n} - \log \mathbb{E}[\hat{f}_{B'_n}]|^2] \\ &\quad + 3(\log \mathbb{E}[\hat{f}_{B'_n}])^2 \mathbb{E}[|\log \hat{f}_{B'_n} - \log \mathbb{E}[\hat{f}_{B'_n}]|] + |\log \mathbb{E}[\hat{f}_{B'_n}]|^3. \end{aligned}$$

By Corollary 3.3,  $\log \mathbb{E}[\hat{f}_{B'_n}] \xrightarrow{n \rightarrow \infty} \log \mathbb{E}[f(\xi_0)]$ . In view of (f3) and since  $f$  is continuous, any power of this quantity is also bounded. Thus, it suffices to show that  $\mathbb{E}[|\log \hat{f}_{B'_n} - \log \mathbb{E}[\hat{f}_{B'_n}]|^3] < \infty$ . For  $n \in \mathbb{N}$  large, (4.2), (4.3) and assumption (f3) yield

$$\mathbb{E}[|\log \hat{f}_{B'_n} - \log \mathbb{E}[\hat{f}_{B'_n}]|^3] \leq \frac{8\mathbb{E}[|\hat{f}_{B'_n} - \mathbb{E}[\hat{f}_{B'_n}]|^3]}{c_0^3}$$

for  $n \in \mathbb{N}$  large, hence it suffices to prove that  $\mathbb{E}[|\hat{f}_{B'_n}|^3]$  is finite. Due to the Campbell theorem,

$$\begin{aligned} \mathbb{E}[|\hat{f}_{B'_n}(\xi'_0)|^3] &= \frac{1}{\lambda^2 |B'_n|^2} \mathbb{E}[F_n^3(\xi'_0, \xi_1)] + \frac{1}{\lambda |B'_n|} \mathbb{E}[F_n^2(\xi'_0, \xi_1) F_n(\xi'_0, \xi_2)] \\ &\quad + \mathbb{E}[F_n(\xi'_0, \xi_1) F_n(\xi'_0, \xi_2) F_n(\xi'_0, \xi_3)], \end{aligned} \tag{5.6}$$

where  $\xi_1, \xi_2, \xi_3$  are independent copies of  $\xi'_0$ . Moreover, following the proof of Lemma 3.6 we find constants  $C_\theta, K_0 > 0$  such that for  $n \in \mathbb{N}$  large enough,

$$\mathbb{E}[F_n^3(\xi'_0, \xi_1)] \leq \frac{C_\theta^2 K_0^2}{b_n^{2p}} (1 + o(1)) \mathbb{E}[f(\xi'_0)],$$

$$\mathbb{E}[F_n^2(\xi'_0, \xi_1) F_n(\xi'_0, \xi_2)] \leq \frac{C_\theta K_0}{b_n^p} (1 + o(1)) \mathbb{E}[f^2(\xi'_0)],$$

as well as

$$\mathbb{E}[F_n(\xi'_0, \xi_1) F_n(\xi'_0, \xi_2) F_n(\xi'_0, \xi_3)] \leq (1 + o(1)) \int_M f(\eta)^4 d\nu_g(\eta) = (1 + o(1)) \mathbb{E}[f^3(\xi'_0)].$$

Plugging this into (5.6) we obtain

$$\mathbb{E}[|\hat{f}_{B'_n}|^3] \leq \frac{2C_\theta^2 K_0^2}{\lambda^2 b_n^{2p} |B'_n|^2} \mathbb{E}[f(\xi'_0)] + \frac{2C_\theta K_0}{b_n^p \lambda |B'_n|} \mathbb{E}[f^2(\xi'_0)] + 2\mathbb{E}[f^3(\xi'_0)]$$

for  $n \in \mathbb{N}$  sufficiently large. This quantity is bounded because all expressions depending on  $n$  tend to zero as  $n \rightarrow \infty$ .  $\square$

The consequent lemmata show that  $\sigma_n^2$  is uniformly bounded.

**Lemma 5.10.** *There exists  $c_2 > 0$  such that for any  $x_1, x_2 \in B_n$  and  $n \in \mathbb{N}$ ,*

$$\text{Cov}(\log \hat{f}_{B'_n+x_1}, \log \hat{f}_{B'_n+x_2}) \leq c_2 \text{Cov}(\hat{f}_{B'_n+x_1}, \hat{f}_{B'_n+x_2}).$$

*Proof.* Adding and subtracting  $\log \mathbb{E}[\hat{f}_{B'_n+y_1}]$  resp.  $\log \mathbb{E}[\hat{f}_{B'_n+y_2}]$ , Theorem 3.8, (4.3) and assumption (f3) lead to

$$\begin{aligned} & \text{Cov}(\log \hat{f}_{B'_n+x_1}, \log \hat{f}_{B'_n+x_2}) \\ &= \mathbb{E}[(\log \hat{f}_{B'_n+x_1} - \log \mathbb{E}[\hat{f}_{B'_n}]) (\log \hat{f}_{B'_n+x_2} - \log \mathbb{E}[\hat{f}_{B'_n}])] - (\mathbb{E}[\log \hat{f}_{B'_n}] - \log \mathbb{E}[\hat{f}_{B'_n}])^2 \\ &\leq \frac{4}{c_0^2} \text{Cov}(\hat{f}_{B'_n+x_1}, \hat{f}_{B'_n+x_2}) \end{aligned}$$

for  $n \in \mathbb{N}$  sufficiently large. The result now follows for any  $n \in \mathbb{N}$  with a constant  $c_2 > 0$  (maybe different from  $4/c_0^2$ ).  $\square$

**Lemma 5.11.** *There exists  $c_3 > 0$  such that for any  $n \in \mathbb{N}$  and  $x_1, x_2 \in B_n$ ,*

$$\text{Cov}(\hat{f}_{B'_n+x_1}, \hat{f}_{B'_n+x_2}) \leq \frac{c_3 |(B'_n + x_1) \cap (B'_n + x_2)|}{\lambda |B'_n|^2}.$$

*Proof.* Applying the Campbell theorem,

$$\begin{aligned}
\text{Cov}(\hat{f}_{B'_n+x_1}, \hat{f}_{B'_n+x_2}) &= \mathbb{E}[\hat{f}_{B'_n+x_1} \hat{f}_{B'_n+x_2}] - (\mathbb{E}[\hat{f}_{B'_n}])^2 \\
&= \frac{1}{\lambda^2 |B'_n|^2} \mathbb{E} \left[ \sum_{y \in \Pi \cap (B'_n+x_1) \cap (B'_n+x_2)} F_n(\xi_y, \xi'_{x_1}) F_n(\xi_y, \xi'_{x_2}) \right] \\
&\quad + \frac{1}{\lambda^2 |B'_n|^2} \mathbb{E} \left[ \sum_{\substack{y_1 \in \Pi \cap (B'_n+x_1) \\ y_2 \in \Pi \cap (B'_n+x_2)}}^{\neq} F_n(\xi_{y_1}, \xi'_{x_1}) F_n(\xi_{y_2}, \xi'_{x_2}) \right] - (\mathbb{E}[F_n(\xi_0, \xi'_{x_1})])^2 \\
&= \frac{|(B'_n+x_1) \cap (B'_n+x_2)|}{\lambda |B'_n|^2} \mathbb{E}[F_n(\xi_0, \xi'_{x_1}) F_n(\xi_0, \xi'_{x_2})] \\
&\quad + \frac{|(B'_n+x_1) \cap (B'_n+x_2)|}{\lambda |B'_n|^2} (\mathbb{E}[F_n(\xi_0, \xi'_{x_1})])^2.
\end{aligned}$$

Further, it follows from (3.8) that for  $n \in \mathbb{N}$  large enough

$$\begin{aligned}
\mathbb{E}[F_n(\xi_0, \xi'_{x_1}) F_n(\xi_0, \xi'_{x_2})] &= \int_{M^3} F_n(\mu, z) F_n(z, \eta) f(\mu) f(z) f(\eta) d\nu_g(\mu, z, \eta) \\
&= (1 + o(1)) \int_M f(z)^3 d\nu_g(z) = (1 + o(1)) \mathbb{E}[f^2(\xi_0)]
\end{aligned}$$

as well as

$$\mathbb{E}[F_n(\xi_0, \xi'_{x_1})] = \int_{M^2} F_n(\mu, z) f(\mu) f(z) d\nu_g(\mu, z) = (1 + o(1)) \mathbb{E}[f(\xi_0)].$$

Thus the assertion holds with  $c_3 = 2\mathbb{E}[f^2(\xi_0)] + 4(\mathbb{E}[f(\xi_0)])^2 > 0$  for  $n \in \mathbb{N}$  large and for any  $n \in \mathbb{N}$  with maybe a different constant  $c_3 > 0$ .  $\square$

Finally, by Corollary 3.3 and analogous arguments involved in (4.2)-(4.4) we have that  $\log \hat{f}_{B'_n}(\xi_0)$  converges to  $\log f(\xi_0)$  in  $L^2$ . Therefore,  $\mathbb{E}[\log^2 \hat{f}_{B'_n}] \rightarrow \mathbb{E}[\log^2 f(\xi_0)]$  as  $n \rightarrow \infty$  and since  $\mathbb{E}[\log^2 f(\xi_0)] < L_1$  by assumption (L1),  $\mathbb{E}[\log^2 \hat{f}_{B'_n}]$  can be bounded by some constant  $\tilde{L}_1 > 0$  uniformly on  $n \in \mathbb{N}$ . On the other hand, Lemma 5.10, Lemma 5.11 and the  $m_n$ -dependence yield

$$\begin{aligned}
\int_{\mathbb{R}^d} |\text{Cov}(\log \hat{f}_{B'_n}, \log \hat{f}_{B'_n+y})| dy &= \int_{B'_n} |\text{Cov}(\log \hat{f}_{B'_n}, \log \hat{f}_{B'_n+y})| dy \\
&\leq \frac{c_1 c_2}{\lambda |B'_n|^2} \int_{B'_n} |B'_n \cap (B'_n + y)| dy = \frac{c_1 c_2}{\lambda^2 2^d} < \infty.
\end{aligned}$$

The next lemmata ensure that  $\sigma_n^2$  can be uniformly bounded from below. Recall that we are assuming that the density  $f$  is continuous.

**Lemma 5.12.** *The estimator  $\hat{f}_{B'_n+y}(\xi'_y)$  is uniformly bounded with respect to  $y \in \mathbb{R}_+^d$  and  $n \in \mathbb{N}$  almost surely.*

*Proof.* By stationarity it suffices to prove the assertion for  $\hat{f}_{B'_n}(\xi_0)$ . Note that  $\xi_0$  is a generic mark that is independent of the MPP  $\Psi$ . From Theorem 3.8 and since  $M$  is compact and  $f$  continuous, we have that  $\hat{f}_n(\eta) \xrightarrow{n \rightarrow \infty} f(\eta) \leq \|f\|_\infty$  a.s., and hence  $\hat{f}_n(\eta) \leq \|f\|_\infty + \varepsilon$  a.s. for any  $\varepsilon > 0$  and  $n \in \mathbb{N}$ . The same holds for  $\hat{f}_{B'_n}(\xi_0)$ .  $\square$

**Lemma 5.13.** *There exists  $c_4 > 0$  such that*

$$\liminf_{n \rightarrow \infty} \int_{B'_n} \text{Cov}(\log \hat{f}_{B'_n}(\xi_0), \log \hat{f}_{B'_n+y}(\xi'_y)) dy \geq c_4.$$

*Proof.* Since  $\Pi$  is a Poisson point process, we know from [7] that it is positively associated. On the other hand, the random variables  $\{\xi'_y\}_{y \in \mathbb{R}_+^d}$  are positively associated as well because they are i.i.d. (see [6, Theorem 1.8]). Therefore, by [6, Corollary 1.9], the random field  $\{\hat{f}_{B'_n+y}(\xi'_y)\}_{y \in \mathbb{R}_+^d}$  is positively associated. Using the characterization of positively associated random fields given in [6, Remark 1.4], this means that for any non-decreasing functions  $h, g: \mathbb{R} \rightarrow \mathbb{R}$  such that the expectations forming the covariance  $\text{Cov}(h(\hat{f}_{B'_n+y_1}), g(\hat{f}_{B'_n+y_2}))$  exist,  $\text{Cov}(h(\hat{f}_{B'_n+y_1}), g(\hat{f}_{B'_n+y_2})) \geq 0$ . In view of Lemma 5.9 we thus have  $\text{Cov}(\log \hat{f}_{B'_n+y_1}, \log \hat{f}_{B'_n+y_2}) \geq 0$  and since  $\log$  is an increasing function, the random field  $\{\log \hat{f}_{B'_n+y}\}_{y \in \mathbb{R}_+^d}$  is also positively associated.

From Lemma 5.12 we know that  $\hat{f}_{B'_n} \leq \|f\|_\infty + \varepsilon$  a.s. for large  $n \in \mathbb{N}$ , and following the proof of [6, Theorem 5.3] with the exponential function, we obtain

$$\text{Cov}(\log \hat{f}_{B'_n}, \log \hat{f}_{B'_n+y}) \geq \frac{1}{2(\|f\|_\infty + \varepsilon)^2} \text{Cov}(\hat{f}_{B'_n}, \hat{f}_{B'_n+y}).$$

Together with the calculations in the proof of Lemma 5.11, this yields

$$\begin{aligned} \int_{\mathbb{R}^d} \text{Cov}(\log \hat{f}_{B'_n}, \log \hat{f}_{B'_n+y}) dy &\geq \frac{\mathbb{E}[f^2(\xi_0)] + (\mathbb{E}[f(\xi_0)])^2}{4(\|f\|_\infty + \varepsilon)^2 \lambda |B'_n|^2} \int_{B'_n} |B'_n \cap (B'_n + y)| dy \\ &= \frac{\mathbb{E}[f^2(\xi_0)] + (\mathbb{E}[f(\xi_0)])^2}{4(\|f\|_\infty + \varepsilon)^2 \lambda m_n^{2d}} \left( \int_0^{m_n} (m_n - y) dy \right)^d = \frac{\mathbb{E}[f^2(\xi_0)] + (\mathbb{E}[f(\xi_0)])^2}{(\|f\|_\infty + \varepsilon)^2 \lambda 2^{d+2}} =: c_4 > 0 \end{aligned}$$

and the result follows with maybe a different constant  $c_4$ .  $\square$

*Proof of Theorem 5.7.* Recall that  $X_{n,y} = \frac{1}{\sqrt{|B_n|\sigma_n}} (-\log \hat{f}_{B'_n+y}(\xi_y^*) + \mathbb{E}[\log \hat{f}_{B'_n}(\xi_0)])$ . On the one hand, applying the Cauchy-Schwartz inequality, Lemma 5.9 and Lemma 5.13, we get for  $n \in \mathbb{N}$  large

$$\mathbb{E}[|X_{n,0}|^3] \leq \frac{8\mathbb{E}[|\log \hat{f}_{B'_n}(\xi_0^*)|^3]}{|B_n|^{3/2} \sigma_n^3} \leq \frac{8c_1}{|B_n|^{3/2} \sigma_n^3} \leq \frac{8a}{|B_n|^{3/2}}$$

with  $a \geq c_1(\lambda c_4)^{-3/2}$ . Corollary 5.2 and the bound in Remark 5.3 finally yield

$$\sup_{x \in \mathbb{R}} |F_n(x) - \Phi(x)| \leq \frac{600a\lambda(1 + \lambda^2 + \lambda^3)(10|B'_n|^{1/d} + 11)^{2d}}{|B_n|^{1/2}}$$

as we wanted to prove. □
